

# Echo - Idea

## Introduction

As an echo is about reflecting the sound from one place to another, so is echo - a product made by Randish.

Echo is a reflection of everything in the application into code, simplifying documentation process for million of developers worldwide.

It creates both internal and external documentation.

Internal such as describing the application and how each file work between 4 and 5 lines

External such as user manuals, FAQs, etc.

## How does it work exactly?

### A. Add the project

Using Github we index the project and look first into the .gitignores to skip the large files. However this is not important as the .gitingore does not upload the files to github anyway, but its good to see anyway.

### B. Scanning

Then the program scans through the files and summarizes each files usage and connectivity to other files. These summaries are saved locally.

We then gain insight about the files and their connections to other files in the project

This gives insight to the project for the whole and proceeds with allowing the user to produce documentation whether that is to automate.

## **C. Grammar check and auto complete**

## **D. Rehash and Re-write**

You can rewrite your written sentences in a specific way and characterize it for the audience type. Or if you want you can reference a Design Methology for your company and the documentation can work with it.

!!!ALL WIUTHOUT USING LLMS AND AI!!!
